D-Dimer	0.62	ug/mlFEU	H	0.00-0.52	07/04/2017 10:32am	07/04/2017 12:06pm	<p>Elevations in D-dimer levels can be seen due to any activation of the coagulation system as well as some systemic conditions (e.g. liver disease, cancers, pregnancy), and are not specific for Deep Venous Thrombosis (DVT) or Disseminated Intravascular Coagulation (DIC).</p> <p>Cut-off Value less than or equal to 0.52 ug/ml FEU</p> <p>Normal levels of D-dimer can be useful to exclude a diagnosis of DVT with reasonable negative-predictive value in situations where the clinical suspicion (prior probability) is low, such as in some outpatients presenting in the ED, and thus avoiding more intensive or invasive studies. Therefore, clinical correlation is recommended when using this test. This D-dimer test should not be used to exclude a DVT diagnosis in: children; patients for which prior probability for DVT is moderate or higher, patient already on anticoagulant therapy, patients for which significant time has elapsed since the presumed thrombotic event (D-dimer half-life about 6-8 hours); patients with suspected upper extremity or distal lower extremity (below knee) thrombosis.</p>
